

Recognition and referral of suspected prostate cancer

Key prostate cancer statistics

27%

of all new cancer cases in males (2016-18)¹

Highest

incidence in older men, Black men and those with family history²

85%

diagnosed via primary care, either through routine or urgent suspected referral (2018)³

100%

will survive for 5 years or more if they are diagnosed at stage 1¹

49%

will survive for 5 years or more if diagnosed at stage 4¹

What you need to know about the PSA test

The PSA test is a blood test that detects the level of a protein called prostate specific antigen (PSA) in the blood. PSA is a protein produced by both normal and cancerous prostate cells and it is normal for all people with a prostate to have some PSA in their blood. The PSA test is used in asymptomatic and symptomatic contexts.

Considerations if you request a PSA test:

- people can have a higher PSA as they get older
- cancer can be present with lower PSA levels
- PSA levels can be increased by a number of things including UTIs, exercising vigorously and ejaculation
- before offering a PSA test discuss the benefits and limitations of the test to enable the person to make an informed choice

Benefits & limitations of PSA testing

NICE recommend providing the following information and advice prior to offering a PSA test to enable the person to make an informed choice⁴:

Benefits of PSA testing include:

- prostate cancer may be detected before symptoms develop and may extend life or facilitate a complete cure

Limitations and risks of PSA testing include:

- **false-negative PSA tests** – about 15% of asymptomatic people with a normal PSA level may have prostate cancer
- **false-positive PSA tests** – about 75% of people with a raised PSA level have a negative prostate biopsy
- **false-positive PSA test may lead to invasive investigations**, such as prostate biopsy, and there may be adverse effects
- **unnecessary treatment** – slow growing tumours are common and may not cause any symptoms or shorten life

Why don't we have a prostate cancer screening programme?

The UK National Screening Committee doesn't currently recommend screening for prostate cancer because⁵:

- it is unclear how PSA screening impacts prostate cancer outcomes, specifically death due to prostate cancer
- there are many harms of PSA screening, such as incorrect diagnosis and complications from further testing and treating
- there is not enough evidence at present to show that there are better tests than PSA
- there is no single treatment that is definitely better for patients with early-stage prostate cancer

CRUK have produced an infographic summarising the evidence for **Prostate Cancer Screening** (2022)

Diagnosing prostate cancer: where are we now?

The diagnostic pathway for prostate cancer has been changing with the implementation of multiparametric MRI (mpMRI). mpMRI is now widely available for use before biopsy.

There is some evidence to suggest that mpMRI can detect more clinically significant prostate cancers than the PSA test, which could help mitigate some of the risks associated with the PSA test, such as biopsy complications, overdiagnosis, and overtreatment.

Research is ongoing to explore:

- optimising the PSA test, e.g. by combining with other patient factors or test results
- risk prediction models, including genetic risk scores
- using AI to support current diagnostics
- a screening trial to address current evidence gap

What can health professionals do to support the timely referral of suspected prostate cancer?

Act on clinical suspicion with consideration of risk factors such as family history and Black ethnicity

Be aware of the potential challenges associated with remote consultation

Conduct face to face appointments/testing with patients if there is suspicion

Consider a digital rectal examination (DRE) and a suspected cancer referral for patients with an abnormal DRE. A normal DRE does not rule out prostate cancer

Consider a discussion with a urologist if you feel it would be helpful, take advantage of Advice and Guidance channels (available in England only)

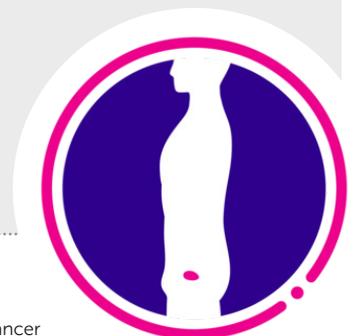

Be aware of and feel confident discussing the benefits and limitations of the PSA test with patients

Be aware if mpMRI is available in your area as it can detect more clinically significant prostate cancers than the PSA test

Safety-netting is vital for all patients, whether they're being referred for tests or specialist advice, or not
